## 1 Introduction

This report is an attempt to explain optimizations in presence of imperfectly nested loops in a crisp and clear way. It has been adapted from the sections 6.4 and 6.5 of the book [1].

## 2 A Short Overview

When an imperfectly loop nest (Section 3) is encountered, the actions taken can be categorised into the following cases:

**Case 1** *When the outermost loop can be parallelized*, parallelize the loop and move further into its body to look for more optimizations.

*An algorithmic approach is discussed ahead*

**Case 2** If the *outermost loop cannot be parallelized*, then maximally distributing it around the statements in its body, can be an effective transformation. This step will create further loop nests, which may lead to the following cases:

**Case 2.1** *Perfectly nested loop nests*. In this case use the perfect nest loop optimization algorithm.

**Case 2.1** *Imperfectly nested loop nests*. This is a result of a *tight recurrence* (a cyclic dependency) involving a statement and an inner loop. In this case it is best to leave the loop sequential and move into its body to look for other optimizations.

**Case 3** *The outer loop can neither be parallelized nor distributed*. Then leave the loop sequential and move into its body to look for other possible optimizations.
